The use of Relative Retention Times may be useful to attempt to initially identify the presence of α - and β -pinenes. PAMS AutoGC systems are running a consistent GC method can produce robust retention times between sites and across years.

Date	Site	RT	Retention Times		
			Toluene	α -Pinene	β -Pinene
8/26/2021	S DeKalb, GA	RT	23.930	33.494	35.255
		RRT	12.124	21.688	23.449
		RRT Tol		9.564	11.325
8/26/2021	Garinger, NC	RT	24.159	33.692	35.457
		RRT	12.057	21.590	23.355
		RRT Tol		9.533	11.298

AutoGC Systems: Pinenes

AutoGC Systems: Pinenes

► Summary

- Pinenes appear to be somewhat stable in aluminum cylinders in dry N₂ for prolonged periods as single species and at ppmC concentrations.
- Pinenes blends in dry N₂ in Silco treated canisters are also stable for short periods of time at low ppmC levels.
- However, injection either by short direct injection or by internal standard injection onto either T17 or T20 traps results in degradation using the PAMS AutoGC methods
- Degradation does not appear to be related to GCFID performance since direct injection on similar systems without concentration appear to remain intact.
- Breakdown appears to be similar between He or H₂ carrier.
- Lowering trap desorb temperature does not appear to reduce pinene decomposition.
- The determination of pinene retention times at sites with substantial forestation are easily demonstrated and confirmed by time series review.
- Using relative retention time to Toluene in PAMS AutoGC standard methods results in reasonably accurate determination of predicted retention times based on data from sites with known pinene contributions.
